

An illustration of a landscape with a brown ground, a green tree on the right, and a small orange figure in the center. A large, light-colored, curved shape resembling a cloud or smoke plume is on the left. The text "Sustainable Development" is written in white on a brown background at the bottom.

Sustainable Development

An identical illustration to the one on the left, featuring a brown ground, a green tree, a small orange figure, and a light-colored curved shape, with the text "Sustainable Development" at the bottom.

Sustainable Development

Chapter 5

DTC and resource efficiency

Resource efficiency in the production function

- The aggregate model
- Problems regarding the DTC model

$$y = F(A_L L, A_R R).$$

$$y = (A_L L)^\alpha (A_R R)^{1-\alpha} = A_L^\alpha R^{1-\alpha}.$$

$$y = \min\{A_L L, A_R R\}.$$

$$y = [\gamma(A_L L)^\epsilon + (1 - \gamma)(A_R R)^\epsilon]^{1/\epsilon}.$$

Resource efficiency in the production function

- Resource efficiency in the production function
- Foundations of an aggregate DTC model
- The aggregate model
- Problems regarding the DTC model

$$y = (A_L L)^\alpha (A_R R)^{1-\alpha} = AL^\alpha R^{1-\alpha}.$$

Why not Cobb–Douglas?

Resource efficiency in the production function

- Problems regarding the DTC model

$$y = [\gamma(A_L L)^\epsilon + (1 - \gamma)(A_R R)^\epsilon]^{1/\epsilon}.$$

What values are possible for ϵ ?

Discuss special cases.

Advantages of CES?

Resource efficiency in the production function

- Resource efficiency in the production function
- Foundations of an aggregate DTC model
- The aggregate model
- Problems regarding the DTC model

Assume an economy with 10 people on an island, and 10 trees/week wash up on the beach. Furthermore, the islanders have a technology called 'knives' which allows them to cut the trees into planks, which can rapidly be made into houses (final product). They manage to make 0.01 houses per week.

What do they need more of to boost their rate of housebuilding? Suggest values for the elasticity of substitution between the inputs, and knowledge levels. Explain briefly.

Resource efficiency in the production function

- Resource efficiency in the production function
- Foundations of an aggregate DTC model
- The aggregate model
- Problems regarding the DTC model

Now assume that the islanders invent a technology called 'sawmills' (and are somehow able to obtain the necessary capital goods). What do they need more of now in order to boost their rate of housebuilding? Suggest new values for the knowledge levels. Explain briefly.

$$\frac{Z_L}{Z_R} = \left(\frac{A_L L}{A_R R}\right)^\epsilon = \left(\frac{A_L/w_L}{A_R/w_R}\right)^{\epsilon/(1-\epsilon)} = \frac{w_L L}{w_R R}$$

Assume $A_{Lt} = (A_{Lt-1}/\zeta_L) Z_{Lt}^\phi$

and $A_{Rt} = (A_{Rt-1}/\zeta_R) Z_{Rt}^\phi$,

so $\frac{A_{Lt}}{A_{Rt}} = \frac{A_{Lt-1}}{A_{Rt-1}} \frac{\zeta_R}{\zeta_L} \left(\frac{Z_{Lt}}{Z_{Rt}}\right)^\phi$.

The aggregate model

- Resource efficiency in the production function
- Foundations of an aggregate DTC model
- The aggregate model
- Problems regarding the DTC model

Assume economy on b.g.p. with constant Z_L/Z_R , hence (below) A_L/A_R changing at constant rate.

Assume w_L/w_R grows (exogenously) at a constant rate. Then (right) L/R must fall at the same rate. And (right) A_L/A_R must rise at that rate.

And we know that there is some level of Z_L/Z_R (and hence A_L/A_R) which yields this rate.

So a b.g.p. exists on which factor shares are constant!

$$\frac{z_{li}}{z_{ri}} = \left(\frac{A_{li}l_i}{A_{ri}r_i} \right)^\epsilon = \frac{w_L l_i}{w_R r_i}$$

$$\frac{Z_L}{Z_R} = \left(\frac{A_L L}{A_R R} \right)^\epsilon = \left(\frac{A_L/w_L}{A_R/w_R} \right)^{\epsilon/(1-\epsilon)} = \frac{w_L L}{w_R R}$$

$$\begin{array}{ll} \text{Assume} & A_{Lt} = (A_{Lt-1}/\zeta_L) Z_{Lt}^\phi \\ & \text{and} \\ & A_{Rt} = (A_{Rt-1}/\zeta_R) Z_{Rt}^\phi, \\ \text{so} & \frac{A_{Lt}}{A_{Rt}} = \frac{A_{Lt-1}}{A_{Rt-1}} \frac{\zeta_R}{\zeta_L} \left(\frac{Z_{Lt}}{Z_{Rt}} \right)^\phi. \end{array}$$

The aggregate model

- Problems regarding the DTC model

Is the b.g.p. stable?

Intuition. Assume the economy is on a b.g.p., and then there is a small shock such that the quantity of R increases more than expected (or the price of R decreases if prices are exogenous and quantities endogenous).

What happens to the factor share of R ? Investment Z_R/Z_L ? And $A_R R / (A_L L)$ in the long run?

The b.g.p. is stable, as long as $\epsilon < 0$.

The aggregate model

- Resource efficiency in the production function
- Foundations of an aggregate DTC model
- The aggregate model
- Problems regarding the DTC model

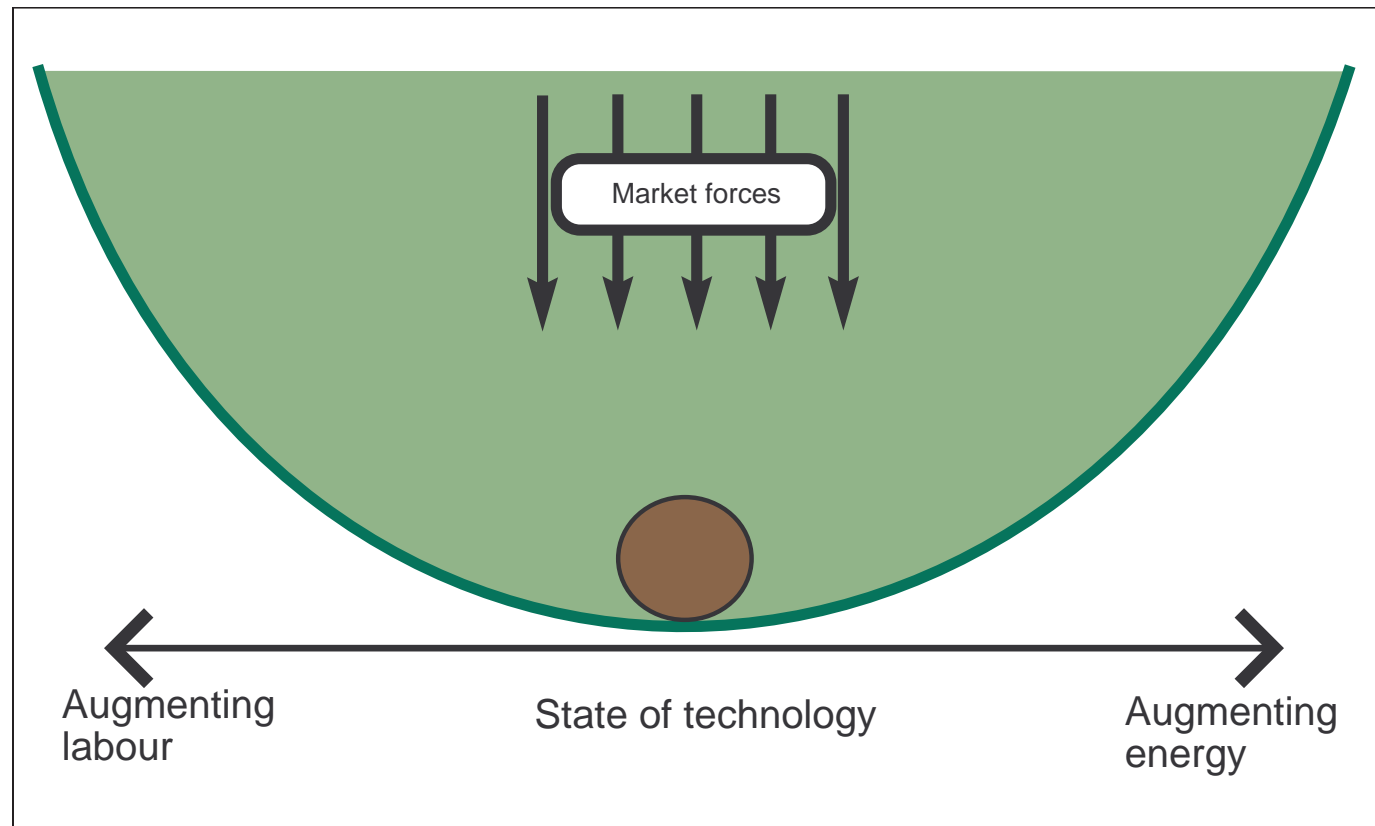

Figure 1: Illustration of how relative prices (the shape of the economic landscape) determine the relative levels of technology augmenting labour and energy.

The aggregate model

- Resource efficiency in the production function
- Foundations of an aggregate DTC model
- The aggregate model
- Problems regarding the DTC model

On a b.g.p.,

$$\frac{A_L L}{A_R R}$$

is constant. Therefore the factor shares are constant. The long-run aggregate production function 'appears to be' Cobb–Douglas!

$$y = AL^{1-\alpha}R^\alpha.$$

Problems regarding the DTC model

- Resource efficiency in the production function
- Foundations of an aggregate DTC model
- The aggregate model
- Problems regarding the DTC model

Problems regarding the DTC model

- Resource efficiency in the production function
- Foundations of an aggregate DTC model
- The aggregate model
- Problems regarding the DTC model

The model predicts that if w_R is constant while w_L increases, then A_R/A_L should decline.

We do not observe such a decline. In fact A_R seems to grow at least as fast as A_L , at least in the case of energy where there is clear evidence.

In the model, A_R is the efficiency of resources in making widgets. If it grows, R/Y (resources per widget) must decline. But R/Y has not declined historically. Why not?

Problems regarding the DTC model

- Resource efficiency in the production function
- Foundations of an aggregate DTC model
- The aggregate model
- Problems regarding the DTC model

The model of knowledge growth makes no sense.

$$A_{lit} = (A_{Lt-1}/\zeta_L)z_{lit}^\phi;$$
$$A_{rit} = (A_{Rt-1}/\zeta_R)z_{rit}^\phi.$$

Growth in A_R should be linked (strongly) to the stock of labour-augmenting knowledge A_L .

If we put such links in the model then A_R grows even when w_R is constant, but the model no longer matches the quantity data since R/Y declines.
